

Daily Workflow — Read This Before You Start Working

The mental model: things you do ONCE per computer, versus things you do EVERY SINGLE TIME you sit down to work.

One-Time Setup (do once, never repeat)

1. Clone the repo: `git clone https://github.com/RaedBafadhl/Talk-to-my-data.git`
2. `cd Talk-to-my-data`
3. Create your venv: `python -m venv venv`
4. Activate it (see below), then: `pip install -r requirements.txt`
5. Copy `.env.example` to `.env`, fill in the real `GCP_PROJECT_ID` (`Project_ID = tgs-talk-to-data`)
6. Run `gcloud auth application-default login`
7. Confirm everything's linked: `python scripts/verify_setup.py` — should show a success message

Every Single Time You Sit Down to Work

1. Open your terminal
2. `cd` into the project folder
3. Activate your venv:
 - Windows (Command Prompt): `venv\Scripts\activate`
 - Windows (PowerShell): `venv\Scripts\Activate.ps1`
 - Mac/Linux: `source venv/bin/activate`

You'll know it worked because your prompt shows (venv) at the start.

4. `git pull` — always do this before starting, so you're working on top of everyone else's latest changes, not an outdated copy
5. Do your work
6. Save your progress: `git add .` then `git commit -m "short description"` then `git push`
7. Close your terminal whenever — nothing needs to stay running

The Full Loop, Visually

Sit down to work

```
-> cd into project folder
-> activate venv
-> git pull (get teammates' latest work)
-> write/edit code
-> test it
-> git add, commit, push (share your work)
-> close terminal, done for now
```

Repeat this every time, for every person.

Team Rules:

- Pull before you push — if git push gets rejected because someone else pushed first, run git pull again to merge their changes in before trying to push yours.
- If requirements.txt changes (someone adds a new package), everyone needs to re-run pip install -r requirements.txt (with venv active) to get it too — this doesn't happen automatically.
- Never commit your own .env file — it's already gitignored, but double-check if you ever see it listed as a change before committing.

If Something Feels Broken

Most "it's not working" moments trace back to one of these three:

1. Forgot to activate the venv (check for (venv) in your prompt)
2. Forgot to git pull, so you're missing a teammate's recent change
3. Forgot to pip install -r requirements.txt after it changed
